Description

Analyzing data with full-information maximum likelihood with auxiliary variables. The techniques used to account for auxiliary variables are both extra-dependent-variables and saturated-correlates approaches (Enders, 2008). The extra-dependent-variables approach is used for exogenous varibles in the model (see fixed.x attribute when fitting the lavaan model). For other variables, the saturated-correlates approach is used. WARNINGS: this function does not work for all models. See the examples below.

Usage

```
auxiliary(object, aux, ...)
```

Arguments

object	The lavaan object or the parameter table
aux	The list of auxiliary variable
	The additional arguments in the lavaan function.

auxiliary 3

Value

The lavaanStar object which contains the original lavaan object and the additional values of the null model, which need to be adjusted to account for auxiliary variables.

Author(s)

Sunthud Pornprasertmanit (University of Kansas; <psunthud@ku.edu>)

clipboard_saveFile 5

Description

Copy or save the result of lavaan object into a clipboard or a file. From the clipboard, users may paste the result into the Microsoft Excel or spreadsheet application to create a table of the output.

Usage

```
clipboard(object, what="summary", ...)
saveFile(object, file, what="summary", tableFormat=FALSE, ...)
```

Arguments

object The lavaan object

what The attributes of the lavaan object to be copied in the clipboard. "summary"

is to copy the screen provided from the summary function. "mifit" is to copy the result from the miPowerFit function. Other attributes listed in the inspect method in the lavaan-class could also be used, such as "coef", "se", "fit",

"samp", and so on.

file A file name used for saving the result

tableFormat If TRUE, save the result in the table format using tabs for seperation. Otherwise,

save the result as the output screen printed in the R console.

... Additional argument listed in the miPowerFit function.

Value

The resulting output will be saved into a clipboard or a file. If using the clipboard function, users may paste it in the other applications.

Author(s)

Sunthud Pornprasertmanit (University of Kansas; <psunthud@ku.edu>)

6 dat2way

```

# Copy the fit measures
clipboard(fit, "fit")
# Save the summary of the lavaan object
saveFile(fit, "out.txt")
# Save the modification indices and the model fit from the miPowerFit function
saveFile(fit, "out.txt", "mifit")
# Save the parameter estimates
saveFile(fit, "out.txt", "coef")
# Save the standard errors
saveFile(fit, "out.txt", "se")
# Save the sample statistics
saveFile(fit, "out.txt", "samp")
# Save the fit measures
saveFile(fit, "out.txt", "fit")
## End(Not run)
```

dat2way

Simulated Dataset to Demonstrate Two-way Latent Interaction

Description

A simulated data set with 2 independent factors and 1 dependent factor where each factor has three indicators

Usage

```
data(dat2way)
```

Format

A data frame with 500 observations of 9 variables.

- **x1** The first indicator of the first independent factor
- x2 The second indicator of the first independent factor
- x3 The third indicator of the first independent factor
- x4 The first indicator of the second independent factor
- x5 The second indicator of the second independent factor
- x6 The third indicator of the second independent factor
- x7 The first indicator of the dependent factor
- x8 The second indicator of the dependent factor
- x9 The third indicator of the dependent factor

dat3way 7

Source

Data was generated by the mvrnorm function in the MASS package.

Examples

head(dat2way)

dat3way

Simulated Dataset to Demonstrate Three-way Latent Interaction

Description

A simulated data set with 3 independent factors and 1 dependent factor where each factor has three indicators

Usage

data(dat3way)

Format

A data frame with 500 observations of 12 variables.

- x1 The first indicator of the first independent factor
- x2 The second indicator of the first independent factor
- x3 The third indicator of the first independent factor
- **x4** The first indicator of the second independent factor
- x5 The second indicator of the second independent factor
- $\mathbf{x6}$ The third indicator of the second independent factor
- **x7** The first indicator of the third independent factor
- x8 The second indicator of the third independent factor
- x9 The third indicator of the third independent factor
- x10 The first indicator of the dependent factor
- x11 The second indicator of the dependent factor
- x12 The third indicator of the dependent factor

Source

Data was generated by the mvrnorm function in the MASS package.

Examples

head(dat3way)

8 findRMSEApower

exLong	Simulated Data set to Demonstrate Longitudinal Measurement Invari-
	ance

Description

A simulated data set with 1 factors with 3 indicators in three timepoints

Usage

```
data(exLong)
```

Format

A data frame with 200 observations of 10 variables.

```
sex Sex of respondents
y1t1 Indicator 1 in Time 1
y2t1 Indicator 2 in Time 1
y3t1 Indicator 3 in Time 1
y1t2 Indicator 1 in Time 2
y2t2 Indicator 2 in Time 2
y3t2 Indicator 3 in Time 2
y1t3 Indicator 1 in Time 3
```

y2t3 Indicator 2 in Time 3y3t3 Indicator 3 in Time 3

Source

Data was generated using the simsem package.

Examples

head(exLong)

findRMSEApower

Find the statistical power based on population RMSEA

Description

Find the proportion of the samples from the sampling distribution of RMSEA in the alternative hypothesis rejected by the cutoff dervied from the sampling distribution of RMSEA in the null hypothesis. This function can be applied for both test of close fit and test of not-close fit (MacCallum, Browne, & Suguwara, 1996)

Usage

```
findRMSEApower(rmsea0, rmseaA, df, n, alpha=.05, group=1)
```

Arguments

rmsea0	Null RMSEA
rmseaA	Alternative RMSEA
df	Model degrees of freedom
n	Sample size of a dataset
alpha	Alpha level used in power calculations
group	The number of group that is used to calculate RMSEA.

Details

This function find the proportion of sampling distribution derived from the alternative RMSEA that is in the critical region derived from the sampling distribution of the null RMSEA. If rmseaA is greater than rmsea0, the test of close fit is used and the critical region is in the right hand side of the null sampling distribution. On the other hand, if rmseaA is less than rmsea0, the test of not-close fit is used and the critical region is in the left hand side of the null sampling distribution (MacCallum, Browne, & Suguwara, 1996).

See Also

- plotRMSEApower to plot the statistical power based on population RMSEA given the sample size
- plotRMSEAdist to visualize the RMSEA distributions
- findRMSEAsamplesize to find the minium sample size for a given statistical power based on population RMSEA

Examples

```
findRMSEApower(rmsea0=.05, rmseaA=.08, df=20, n=200)
```

findRMSEAsamplesize	Find the minimum sample size for a given statistical power based on
	population RMSEA

Description

Find the minimum sample size for a specified statistical power based on population RMSEA. This function can be applied for both test of close fit and test of not-close fit (MacCallum, Browne, & Suguwara, 1996)

Usage

findRMSEAsamplesize(rmsea0, rmseaA, df, power=0.80, alpha=.05, group=1)

Arguments

rmsea0	Null RMSEA
rmseaA	Alternative RMSEA
df	Model degrees of freedom
power	Desired statistical power to reject misspecified model (test of close fit) or retain good model (test of not-close fit)
alpha	Alpha level used in power calculations
group	The number of group that is used to calculate RMSEA.

Details

This function find the minimum sample size for a specified power based on an iterative routine. The sample size keep increasing until the calculated power from findRMSEApower function is just over the specified power. If group is greater than 1, the resulting sample size is the sample size per group.

```
findRMSEAsamplesize(rmsea0=.05, rmseaA=.08, df=20, power=0.80)
```

impliedFactorStat 11

impliedFactorStat

Calculate the model-implied factor means and covariance matrix.

Description

Calculate reliability values of factors by coefficient omega

Usage

```
impliedFactorStat(object)
impliedFactorMean(object)
impliedFactorCov(object)
```

Arguments

object

The lavaan model object provided after running the cfa, sem, growth, or lavaan functions.

Details

The impliedFactorMean function is used to calculated model-implied factor means:

$$\mu = (\boldsymbol{I} - \boldsymbol{B})^{-1} \alpha,$$

where μ is the model-implied factor mean, I is an identity matrix, B is an regression coefficient matrix, and α is a vector of factor intercepts.

The impliedFactorCov function is used to calculated model-implied covariance matrix:

$$\Phi = (\boldsymbol{I} - \boldsymbol{B})^{-1} \Psi (\boldsymbol{I} - \boldsymbol{B})^{-1\prime},$$

where Φ is the model-implied factor covariance matrix, Ψ is the residual factor covariance matrix.

The impliedFactorStat function is used to provide both model-implied means (if the mean structure is estimated) and covariance matrix.

Value

Model-implied factor means or model-implied factor covariance matrix, or both

Author(s)

Sunthud Pornprasertmanit (University of Kansas; <psunthud@ku.edu>)

12 indProd

double-mean cemering, or restaud cemering	indProd	Make products of indicators using no centering, mean centering, double-mean centering, or residual centering
---	---------	--

Description

The indProd function will make products of indicators using no centering, mean centering, double-mean centering, or residual centering. The orthogonalize function is the shortcut of the indProd function to make the residual-centered indicators products.

Usage

```
indProd(data, var1, var2, var3=NULL, match = TRUE, meanC = TRUE,
residualC = FALSE, doubleMC = TRUE, namesProd = NULL)
orthogonalize(data, var1, var2, var3=NULL, match=TRUE, namesProd=NULL)
```

Arguments

data	The desired data to be transformed.
var1	Names or indices of the variables loaded on the first factor
var2	Names or indices of the variables loaded on the second factor
var3	Names or indices of the variables loaded on the third factor (for three-way interaction)
match	Specify TRUE to use match-paired approach (Marsh, Wen, & Hau, 2004). If FALSE, the resulting products are all possible products.
meanC	Specify TRUE for mean centering the main effect indicator before making the products
residualC	Specify TRUE for residual centering the products by the main effect indicators (Little, Bovaird, & Widaman, 2006).
doubleMC	Specify TRUE for centering the resulting products (Lin et. al., 2010)
namesProd	The names of resulting products

Value

The original data attached with the products.

# Mean centering / three-way interaction / match-paired
dat4 <- indProd(attitude[,-1], var1=1:2, var2=3:4, var3=5:6)

# Residual centering / three-way interaction / match-paired
dat5 <- indProd(attitude[,-1], var1=1:2, var2=3:4, var3=5:6, match=FALSE, meanC=FALSE, residualC=TRUE, double-mean centering / three-way interaction / match-paired</pre>
```

dat6 <- indProd(attitude[,-1], var1=1:2, var2=3:4, var3=5:6, match=FALSE, meanC=TRUE, residualC=TRUE, doub.

kurtosis

Finding excessive kurtosis

Description

Finding excessive kurtosis (g2) of an object

Usage

```
kurtosis(object, population=FALSE)
```

Arguments

object A vector used to find a excessive kurtosis

population TRUE to compute the parameter formula. FALSE to compute the sample statistic

formula.

14 kurtosis

Details

The excessive kurtosis computed is g2. The parameter excessive kurtosis γ_2 formula is

$$\gamma_2 = \frac{\mu_4}{\mu_2^2} - 3,$$

where μ_i denotes the *i* order central moment.

The excessive kurtosis formula for sample statistic g_2 is

$$g_2 = \frac{k_4}{k_2^2},$$

where k_i are the i order k-statistic.

The standard error of the excessive kurtosis is

$$Var(\hat{g}_2) = \frac{24}{N}$$

where N is the sample size.

Value

A value of an excessive kurtosis with a test statistic if the population is specified as FALSE

lavaanStar-class 15

lavaanStar-class Class For Representing A (Fitted) Latent Variable Model with Additional Elements

Description

This is the lavaan class that contains additional information about the fit values from the null model. Some functions are adjusted according to the change.

Objects from the Class

Objects can be created via the auxiliary function or runMI.

Slots

call: The function call as returned by match.called().

timing: The elapsed time (user+system) for various parts of the program as a list, including the total time.

Options: Named list of options that were provided by the user, or filled-in automatically.

ParTable: Named list describing the model parameters. Can be coerced to a data.frame. In the documentation, this is called the 'parameter table'.

Data: Object of internal class "Data": information about the data.

SampleStats: Object of internal class "SampleStats": sample statistics

Model: Object of internal class "Model": the internal (matrix) representation of the model

Fit: Object of internal class "Fit": the results of fitting the model

nullfit: The fit-indices information from the null model

imputed: The list of information from running multiple imputation. The first element is the convergence rate of the target and null models. The second element is the fraction missing information. The first estimate of FMI (FMI.1) is asymptotic FMI and the second estimate of FMI (FMI.2) is corrected for small numbers of imputation. The third element is the fit values of the target model by the specified chi-squared methods. The fourth element is the fit values of the null model by the specified chi-square methods.

1004	ingFrom	11 nh n
TOdu	THELLOH	итрпа

Find standardized factor loading from coefficient alpha

Description

Find standardized factor loading from coefficient alpha assuming that all items have equal loadings.

Usage

```
loadingFromAlpha(alpha, ni)
```

Arguments

alpha A desired coefficient alpha value.

ni A desired number of items.

Value

result The standardized factor loadings that make desired coefficient alpha with speci-

fied number of items.

Author(s)

Sunthud Pornprasertmanit (University of Kansas; <psunthud@ku.edu>)

Examples

```
loadingFromAlpha(0.8, 4)
```

longInvariance

Measurement Invariance Tests Within Person

Description

Testing measurement invariance across timepoints (longitudinal) or any context involving the use of the same scale in one case (e.g., a dyad case with husband and wife answering the same scale). The measurement invariance uses a typical sequence of model comparison tests. This function currently works with only one scale.

Usage

```
longInvariance(model, varList, auto = "all", constrainAuto = FALSE,
fixed.x = TRUE, std.lv = FALSE, group=NULL, group.equal="",
group.partial="", warn=TRUE, debug=FALSE, strict = FALSE, quiet = FALSE,
...)
```

longInvariance 17

Arguments

model lavaan syntax or parameter table

varList A list containing indicator names of factors used in the invariance testing, such

as the list that the first element is the vector of indicator names in the first timepoint and the second element is the vector of indicator names in the second timepoint. The order of indicator names should be the same (but measured in

different times or different units).

auto The order of autocorrelation on the measurement errors on the similar items

across factor (e.g., Item 1 in Time 1 and Time 2). If 0 is specified, the autocorrelation will be not imposed. If 1 is specified, the autocorrelation will imposed for the adjacent factor listed in varList. The maximum number can be specified is the number of factors specified minus 1. If "all" is specified, the maximum

number of order will be used.

constrainAuto If TRUE, the function will equate the auto-covariance to be equal within the same

item across factors. For example, the covariance of item 1 in time 1 and time 2

is equal to the covariance of item 1 in time 2 and time 3.

fixed.x See lavaan.
std.lv See lavaan.
group See lavaan.
group.equal See lavaan.
group.partial See lavaan.
warn See lavaan.
debug See lavaan.

strict If TRUE, the sequence requires 'strict' invariance. See details for more informa-

tion.

quiet If TRUE, a summary is printed out containing an overview of the different models

that are fitted, together with some model comparison tests.

... Additional arguments in the lavaan function.

Details

If strict = FALSE, the following four models are tested in order:

- 1. Model 1: configural invariance. The same factor structure is imposed on all units.
- 2. Model 2: weak invariance. The factor loadings are constrained to be equal across units.
- 3. Model 3: strong invariance. The factor loadings and intercepts are constrained to be equal across units.
- 4. Model 4: The factor loadings, intercepts and means are constrained to be equal across units.

Each time a more restricted model is fitted, a chi-square difference test is reported, comparing the current model with the previous one, and comparing the current model to the baseline model (Model 1). In addition, the difference in cfi is also reported (delta.cfi).

If strict = TRUE, the following five models are tested in order:

- 1. Model 1: configural invariance. The same factor structure is imposed on all units.
- 2. Model 2: weak invariance. The factor loadings are constrained to be equal across units.
- 3. Model 3: strong invariance. The factor loadings and intercepts are constrained to be equal across units.

18 longInvariance

4. Model 4: strict invariance. The factor loadings, intercepts and residual variances are constrained to be equal across units.

5. Model 5: The factor loadings, intercepts, residual variances and means are constrained to be equal across units.

Note that if the chi-square test statistic is scaled (eg. a Satorra-Bentler or Yuan-Bentler test statistic), a special version of the chi-square difference test is used as described in http://www.statmodel.com/chidiff.shtml

Value

Invisibly, all model fits in the sequence are returned as a list.

mardiaKurtosis 19

mardiaKurtosis

Finding Mardia's multivariate kurtosis

Description

Finding Mardia's multivariate kurtosis of multiple variables

Usage

mardiaKurtosis(dat)

Arguments

dat

The target matrix or data frame with multiple variables

Details

The Mardia's multivariate kurtosis formula (Mardia, 1970) is

$$b_{2,d} = \frac{1}{n} \sum_{i=1}^{n} \left[\left(X_i - \bar{X} \right)' S^{-1} \left(X_i - \bar{X} \right) \right]^2,$$

where d is the number of variables, X is the target dataset with multiple variables, n is the sample size, S is the sample covariance matrix of the target dataset, and \bar{X} is the mean vectors of the target dataset binded in n rows. When the population multivariate kurtosis is normal, the $b_{2,d}$ is asymptotically distributed as normal distribution with the mean of d(d+2) and variance of 8d(d+2)/n.

Value

A value of a Mardia's multivariate kurtosis with a test statistic

Author(s)

Sunthud Pornprasertmanit (University of Kansas; <psunthud@ku.edu>)

References

mardiaSkew

Finding Mardia's multivariate skewness

Description

Finding Mardia's multivariate skewness of multiple variables

Usage

mardiaSkew(dat)

Arguments

dat

The target matrix or data frame with multiple variables

Details

The Mardia's multivariate skewness formula (Mardia, 1970) is

$$b_{1,d} = rac{1}{n^2} \sum_{i=1}^n \sum_{j=1}^n \left[\left(m{X}_i - ar{m{X}}
ight)' m{S}^{-1} \left(m{X}_j - ar{m{X}}
ight)
ight]^3,$$

where d is the number of variables, X is the target dataset with multiple variables, n is the sample size, S is the sample covariance matrix of the target dataset, and \bar{X} is the mean vectors of the target dataset binded in n rows. When the population multivariate skewness is normal, the $\frac{n}{6}b_{1,d}$ is asymptotically distributed as chi-square distribution with d(d+1)(d+2)/6 degrees of freedom.

Value

A value of a Mardia's multivariate skewness with a test statistic

Author(s)

Sunthud Pornprasertmanit (University of Kansas; <psunthud@ku.edu>)

measurementInvariance 21

measurementInvariance Measurement Invariance Tests

Description

Testing measurement invariance across groups using a typical sequence of model comparison tests.

Usage

```
measurementInvariance(..., strict = FALSE, quiet = FALSE)
```

Arguments

... The same arguments as for any lavaan model. See cfa for more information.

strict If TRUE, the sequence requires 'strict' invariance. See details for more informa-

tion.

quiet If TRUE, a summary is printed out containing an overview of the different models

that are fitted, together with some model comparison tests.

Details

If strict = FALSE, the following four models are tested in order:

- 1. Model 1: configural invariance. The same factor structure is imposed on all groups.
- 2. Model 2: weak invariance. The factor loadings are constrained to be equal across groups.
- 3. Model 3: strong invariance. The factor loadings and intercepts are constrained to be equal across groups.
- 4. Model 4: The factor loadings, intercepts and means are constrained to be equal across groups.

Each time a more restricted model is fitted, a chi-square difference test is reported, comparing the current model with the previous one, and comparing the current model to the baseline model (Model 1). In addition, the difference in cfi is also reported (delta.cfi).

If strict = TRUE, the following five models are tested in order:

- 1. Model 1: configural invariance. The same factor structure is imposed on all groups.
- 2. Model 2: weak invariance. The factor loadings are constrained to be equal across groups.
- 3. Model 3: strong invariance. The factor loadings and intercepts are constrained to be equal across groups.
- 4. Model 4: strict invariance. The factor loadings, intercepts and residual variances are constrained to be equal across groups.
- 5. Model 5: The factor loadings, intercepts, residual variances and means are constrained to be equal across groups.

Note that if the chi-square test statistic is scaled (eg. a Satorra-Bentler or Yuan-Bentler test statistic), a special version of the chi-square difference test is used as described in http://www.statmodel.com/chidiff.shtml

Value

Invisibly, all model fits in the sequence are returned as a list.

miPowerFit

Modification indices and their power approach for model fit evaluation

Description

The model fit evaluation approach using modification indices and their power proposed by Saris, Satorra, and van der Veld (2009, pp. 570-573).

Usage

```
miPowerFit(lavaanObj, stdLoad=0.4, cor=0.1, stdBeta=0.1, intcept=0.2, stdDelta=NULL, delta=NULL)
```

Arguments

lavaanObj	The lavaan model object used to evaluate model fit
stdLoad	The amount of standardized factor loading that one would like to be detected (rejected). The default value is 0.4, which is suggested by Saris and colleagues (2009, p. 571).
cor	The amount of factor or error correlations that one would like to be detected (rejected). The default value is 0.1, which is suggested by Saris and colleagues (2009, p. 571).
stdBeta	The amount of standardized regression coefficients that one would like to be detected (rejected). The default value is 0.1, which is suggested by Saris and colleagues (2009, p. 571).
intcept	The amount of standardized intercept (similar to Cohen's d that one would like to be detected (rejected). The default value is 0.2, which is equivalent to a low effect size proposed by Cohen (1988, 1992).

miPowerFit 23

stdDelta

The vector of the standardized parameters that one would like to be detected (rejected). If this argument is specified, the value here will overwrite the other arguments above. The order of the vector must be the same as the row order from modification indices from the lavaan object. If a single value is specified, the value will be applied to all parameters.

delta

The vector of the unstandardized parameters that one would like to be detected (rejected). If this argument is specified, the value here will overwrite the other arguments above. The order of the vector must be the same as the row order from modification indices from the lavaan object. If a single value is specified, the value will be applied to all parameters.

Details

In the lavaan object, one can inspect the modification indices and expected parameter changes. Those values can be used to evaluate model fit by the method proposed by Saris and colleagues (2009). First, one should evaluate whether the modification index of each parameter is significant. Second, one should evaluate whether the power to detect a target expected parameter change is high enough. If the modification index is not significant and the power is high, there is no misspecification. If the modification index is significant and the power is low, the fixed parameter is misspecified. If the modification index is significant and the power is high, the expected parameter change is investigated. If the expected parameter change is large (greater than the the target expected parameter change), the parameter is misspecified. If the expected parameter change is low (lower than the target expected parameter change), the parameter is not misspecificied. If the modification index is not significant and the power is low, the decision is inconclusive.

Value

A data frame with these variables:

- 1. lhs The left-hand side variable (with respect to the lavaan operator)
- 2. op The lavaan syntax operator: "~~" represents covariance, "=~" represents factor loading, "~" represents regression, and "~1" represents intercept.
- 3. rhs The right-hand side variable (with respect to the lavaan operator)
- 4. group The group of the parameter
- 5. mi The modification index of the fixed parameter
- 6. epc The expected parameter change if the parameter is freely estimated
- 7. target.epc The target expected parameter change that represents the minimum size of misspecification that one would like to be detected by the test with a high power
- 8. std.epc The standardized expected parameter change if the parameter is freely estimated
- 9. std.target.epc The standardized target expected parameter change
- 10. significant.mi Represents whether the modification index value is significant
- 11. high.power Represents whether the power is enough to detect the target expected parameter change
- 12. decision The decision whether the parameter is misspecified or not: "M" represents the parameter is misspecified, "NM" represents the parameter is not misspecified, "EPC:M" represents the parameter is misspecified decided by checking the expected parameter change value, "EPC:NM" represents the parameter is not misspecified decided by checking the expected parameter change value, and "I" represents the decision is inconclusive.

monteCarloMed

Monte Carlo Confidence Intervals to Test Complex Indirect Effects

Description

This function takes an expression for an indirect effect, the parameters and standard errors associated with the expression and returns a confidence interval based on a Monte Carlo test of mediation (MacKinnon, Lockwood, & Williams, 2004).

monteCarloMed 25

Usage

monteCarloMed(expression, ..., ACM=NULL, rep=20000, CI=95, plot=FALSE, outputValues=FALSE)

Arguments

expression	A character scalar representing the computation of an indirect effect. Different parameters in the expression should have different alphanumeric values. Expressions can use either addition (+) or multiplication (*) operators.
	Parameter estimates for all parameters named in expression. The order of parameters should follow from expression (the first parameter named in expression should be the first parameter listed in). Alternatively can be a vector of parameter estimates.
ACM	A matrix representing the asymptotic covariance matrix of the parameters described in expression. This matrix should be a symetric matrix with dimensions equal to the number of parameters names in expression. Information on finding the ACOV is popular SEM software is described below.)
rep	The number of replications to compute. Many thousand are reccomended.
CI	Width of the confidence interval computed.
plot	Should the function output a plot of simulated values of the indirect effect?
outputValues	Should the function output all simulated values of the indirect effect?

Details

This function implements the Monte Carlo test of mediation first described in MacKinnon, Lockwood, & Williams (2004) and extends it to complex cases where the indirect effect is more than a function of two parameters. The function takes an expression for the indirect effect, randomly simulated values of the indirect effect based on the values of the parameters (and the associated standard errors) comprising the indirect effect, and outputs a confidence interval of the indirect effect based on the simulated values. For further information on the Monte Carlo test of mediation see MacKinnon, Lockwood, & Williams (2004), Preacher & Selig (in press), and Selig & Preacher (2008). For a Monte Carlo test of mediation with a random effects model see Selig & Preacher (2010).

The asymptotic covariance matrix can be easily found in many popular SEM software applications.

- LISRELIncluding the EC option on the OU line will print the ACM to a seperate file. The file contains the lower triangular elements of the ACM in free format and scientific notation
- MplusInclude the command TECH3; in the OUTPUT section. The ACM will be printed in the output.
- lavaan Use the command vcov on the fitted lavaan object to print the ACM to the screen

Value

A list with two elements. The first element is the point estimate for the indirect effect. The second element is a matrix with values for the upper and lower limits of the confidence interval generated from the Monte Carlo test of mediation. If outputValues=TRUE, output will be a list with a list with the point estimate and values for the upper and lower limits of the confidence interval as the first element and a vector of simulated values of the indirect effect as the second element.

moreFitIndices 27

moreFitIndices

Calculate more fit indices

Description

Calculate more fit indices that are not already provided in lavaan.

Usage

moreFitIndices(object, nPrior = 1)

Arguments

object The lavaan model object provided after running the cfa, sem, growth, or lavaan

functions.

nPrior The sample size on which prior is based. This argument is used to compute

BIC*.

Details

Normed Fit Index (nfi; West, Taylor, & Wu, 2012) is one of the relative fit indices which can be computed by

$$nfi = \frac{\chi_0^2 - \chi_k^2}{\chi_0^2},$$

where χ_k^2 is the chi-square test statistic value of the target model, χ_0^2 is the chi-square test statistic value of the null model

Incremental Fit Index (ifi; West, Taylor, & Wu, 2012) is one of the relative fit indices which can be computed by

$$ifi = \frac{\chi_0^2 - \chi_k^2}{\chi_0^2 - df_k},$$

where df_k is the degree of freedom when fitting the target model

Gamma Hat (gfi*; West, Taylor, & Wu, 2012) is one of the relative fit indices which can be computed by

$$gfi* = \frac{p}{p + 2 \times \frac{\chi_k^2 - df_k}{N - 1}},$$

where N is the sample size, p is the number of variables in the model. This formula assumes equal number of indicators across groups.

Adjusted Gamma Hat (agfi*; West, Taylor, & Wu, 2012) is one of the relative fit indices which can be computed by

$$agfi* = \left(1 - \frac{K \times p \times (p+1)}{2 \times df_k}\right) \times \left(1 - gfi*\right),$$

28 moreFitIndices

where K is the number of group (please refer to Dudgeon, 2004 for the multiple-group adjustment for agfi*).

Corrected Akaike Information Criterion (AICc; Burnham & Anderson, 2003) is the corrected version of aic for small sample size:

$$aicc = f + \frac{2k(k+1)}{N-k-1},$$

where f is the minimized discrepancy function, which is the product of the log likelihood and -2, and k is the number of parameters in the target model.

Expected Value of Cross-Validation Index (ECVI; West, Taylor, & Wu, 2012) is the average discrepancy in the fitted covariance matrices between two samples of equal sample size across all possible combinations of two samples from the same population:

$$ecvi = f + \frac{2 \times k}{N},$$

Stochastic information criterion (sic; Preacher, 2006) is similar to aic or bic. This index will account for model complexity in the model's function form, in addition to the number of free parameters. This index will be provided only the chi-square value is not scaled. sic can be computed by

$$sic = \frac{1}{2} \left(f - \log \det I(\hat{\theta}) \right),$$

where $I(\hat{\theta})$ is the information matrix of the parameters.

Corrected Bayesian Information Criterion (BIC*; Kuha, 2004) is similar to bic but explicitly specifying the sample size on which the prior is based (N_{prior}) .

$$bicc = f + k \log (1 + N/N_{prior}),$$

Hannan-Quinn Information Criterion (hqc; Hannan & Quinn, 1979) is used for model selection similar to aic or bic.

$$hqc = f + 2k \log(\log N),$$

Note that if Satorra-Bentler or Yuan-Bentler's method is used, the fit indices using the scaled chisquare values are also provided.

See nullRMSEA for the further details of the computation of RMSEA of the null model.

Value

- 1. nfi Normed Fit Index
- 2. ifi Incremental Fit Index
- 3. gfi* Gamma Hat
- 4. agfi* Adjusted Gamma Hat
- 5. baseline.rmsea RMSEA of the Baseline (Null) Model
- 6. aicc Corrected Akaike Information Criterion
- 7. ecvi Expected Value of Cross-Validation Index
- 8. sic Stochastic Information Criterion

moreFitIndices 29

- 9. bic* Bayesian Information Criterion with specifying the prior sample size
- 10. hqc Hannan-Quinn Information Criterion
- 11. nfi.scaled Normed Fit Index using Scaled Chi-square
- 12. ifi.scaled Incremental Fit Index using Scaled Chi-square
- 13. gfi*.scaled Gamma Hat using Scaled Chi-square
- 14. agfi*.scaled Adjusted Gamma Hat using Scaled Chi-square
- 15. baseline.rmsea.scaled RMSEA of the Baseline (Null) Model using Scaled Chi-square

30 nullRMSEA

nullRMSEA

Calculate the RMSEA of the null model

Description

Calculate the RMSEA of the null (baseline) model

Usage

nullRMSEA(object, scaled = FALSE, silent=FALSE)

Arguments

object The lavaan model object provided after running the cfa, sem, growth, or lavaan functions.

scaled If TRUE, calculate the null model from the scaled test.

silent If TRUE, do not print anything on the screen.

Details

RMSEA of the null model is calculated similar to the formula provided in the lavaan package. The standard formula of RMSEA is

$$RMSEA = \sqrt{\frac{\chi^2}{N \times df} - \frac{1}{N}} \times \sqrt{G}$$

where χ^2 is the chi-square test statistic value of the target model, N is the total sample size, df is the degree of freedom of the hypothesized model, G is the number of groups. Kenny proposed in his website that

"A reasonable rule of thumb is to examine the RMSEA for the null model and make sure that is no smaller than 0.158. An RMSEA for the model of 0.05 and a TLI of .90, implies that the RMSEA of the null model is 0.158. If the RMSEA for the null model is less than 0.158, an incremental measure of fit may not be that informative."

See http://davidakenny.net/cm/fit.htm.

Value

A value of RMSEA of the null model. This value is hidden. Users may be assigned the output of this function to any object for further usage.

parcelAllocation 31

See Also

- miPowerFit For the modification indices and their power approach for model fit evaluation
- moreFitIndices For other fit indices

Examples

parcelAllocation

Random Allocation of Items to Parcels in a Structural Equation Model

Description

This function generates a given number of randomly generated item-to-parcel allocations, fits a model to each allocation, and provides averaged results over all allocations.

Usage

```
parcelAllocation(nPerPar, facPlc, nAlloc=100, syntax, dataset, names='default', leaveout=0, ...)
```

Arguments

nPerPar	A list in which each element is a vector corresponding to each factor indicating sizes of parcels. If variables are left out of parceling, they should not be accounted for here (there should NOT be parcels of size "1").
facPlc	A list of vectors, each corresponding to a factor, specifying the variables in that factor (whether included in parceling or not). Either variable names or column numbers. Variables not listed will not be modeled or included in output datasets.
nAlloc	The number of random allocations of items to parcels to generate.
syntax	lavaan syntax. If substituted with a file name, parcelAllocation will print output data sets to a specified folder rather than analyzing using lavaan (note for Windows users: file path must be specified using forward slashes).
dataset	Data set. Can be file path or R object (matrix or dataframe). If the data has missing values multiple imputation before parceling is recommended.
names	(Optional) A character vector containing the names of parceled variables.
leaveout	A vector of variables to be left out of randomized parceling. Either variable names or column numbers are allowed.
	Additional arguments to be passed to lavaan

32 parcelAllocation

Details

This function implements the random item to parcel allocation procedure described in Sterba (2011) and Sterba and MccCallum (2010). The function takes a single data set with item level data, randomly assigns items to parcels, fits a structural equation model to the parceled data (using lavaan), and repeats this process for a user specified number of random allocations. Results from all fitted models are summarized and output. For further details on the benefits of the random allocation of itesm to parcels see Sterba (2011) and Sterba and MccCallum (2010).

Value

Estimates A data frame containing results related to parameter estimates with columns cor-

responding to parameter names, average parameter estimates across allocations, the standard deviation of parameter estimates across allocations, the minimum parameter estimate across allocations, the maximum parameter estimate across allocations, the range of parameter estimates across allocations, and the propor-

tions of allocations in which the parameter estimate is significant.

A data frame containing results related to standard errors with columns corre-

sponding to parameter names, average standard errors across allocations, the standard deviation of standard errors across allocations, the minimum standard error across allocations, the maximum standard error across allocations, and the

range of standard errors across allocations.

Fit A data frame containing results related to model fit with columns corresponding

to fit index names, the average of each index across allocations, the standard deviation of each fit index across allocations, the minimum of each fit index across allocations, the maximum of each fit index across allocations, and the

range of each fit index across allocations.

plotProbe 33

plotProbe	Plot the graphs for probing latent interaction	

Description

This function will plot the line graphs representing the simple effect of the independent variable given the values of the moderator.

Usage

```
plotProbe(object, xlim, xlab="Indepedent Variable", ylab="Dependent Variable", ...)
```

Arguments

object	The result of probing latent interaction obtained from probe2WayMC, probe2WayRC, probe3WayMC, or probe3WayRC function.
xlim	The vector of two numbers: the minimum and maximum values of the independent variable
xlab	The label of the x-axis
ylab	The label of the y-axis
	Any addition argument for the plot function

Value

None. This function will plot the simple main effect only.

Plot the sampling distributions of RMSEA

Description

Plots the sampling distributions of RMSEA based on the noncentral chi-square distributions

Usage

```
plotRMSEAdist(rmsea, n, df, ptile=NULL, caption=NULL, rmseaScale = TRUE, group=1)
```

Arguments

rmsea	The vector of RMSEA values to be plotted
n	Sample size of a dataset
df	Model degrees of freedom
ptile	The percentile rank of the distribution of the first RMSEA that users wish to plot a vertical line in the resulting graph
caption	The name vector of each element of rmsea
rmseaScale	If TRUE, the RMSEA scale is used in the x-axis. If FALSE, the chi-square scale is used in the x-axis.
group	The number of group that is used to calculate RMSEA.

Details

This function creates overlappling plots of the sampling distribution of RMSEA based on non-central chi-square distribution (MacCallum, Browne, & Suguwara, 1996). First, the noncentrality parameter (λ) is calculated from RMSEA (Steiger, 1998; Dudgeon, 2004) by

$$\lambda = (N-1)d\varepsilon^2/K,$$

where N is sample size, d is the model degree of freedom, K is the number of groupand ε is the population RMSEA. Next, the noncentral chi-square distribution with a specified degree of freedom

36 plotRMSEApower

and noncentrality parameter is plotted. Thus, the x-axis represent the sample chi-square value. The sample chi-square value can be transformed to the sample RMSEA scale $(\hat{\epsilon})$ by

$$\hat{\varepsilon} = \sqrt{K} \sqrt{\frac{\chi^2 - d}{(N - 1)d}},$$

where χ^2 is the chi-square value obtained from the noncentral chi-square distribution.

- findRMSEAsamplesize to find the minium sample size for a given statistical power based on population RMSEA

Examples

```
plotRMSEAdist(rmsea=c(.05, .08), n=200, df=20, ptile=0.95, rmseaScale = TRUE)
plotRMSEAdist(rmsea=c(.05, .01), n=200, df=20, ptile=0.05, rmseaScale = FALSE)
```

plotRMSEApower

Plot power curves for RMSEA

Description

Plots power of RMSEA over a range of sample sizes

Usage

```
plotRMSEApower(rmsea0, rmseaA, df, nlow, nhigh, steps=1, alpha=.05, group=1, ...)
```

plotRMSEApower 37

Arguments

rmsea0	Null RMSEA
rmseaA	Alternative RMSEA
df	Model degrees of freedom
nlow	Lower sample size
nhigh	Upper sample size
steps	Increase in sample size for each iteration. Smaller values of steps will lead to more precise plots. However, smaller step sizes means a longer run time.
alpha	Alpha level used in power calculations
group	The number of group that is used to calculate RMSEA.
	The additional arguments for the plot function.

Details

This function creates plot of power for RMSEA against a range of sample sizes. The plot places sample size on the horizontal axis and power on the vertical axis. The user should indicate the lower and upper values for sample size and the sample size between each estimate ("step size") We strongly urge the user to read the sources below (see References) before proceeding. A web version of this function is available at: http://quantpsy.org/rmsea/rmseaplot.htm.

Value

1. plot Plot of power for RMSEA against a range of sample sizes

probe2WayMC	Probing two-way interaction on the residual-centered latent interaction
•	

Description

Probing interaction for simple intercept and simple slope for the no-centered or mean-centered latent two-way interaction

Usage

```
probe2WayMC(fit, nameX, nameY, modVar, valProbe)
```

Arguments

fit	The lavaan model object used to evaluate model fit
nameX	The vector of the factor names used as the predictors. The first-order factor will be listed first. The last name must be the name representing the interaction term.
nameY	The name of factor that is used as the dependent variable.
modVar	The name of factor that is used as a moderator. The effect of the other independent factor on each moderator variable value will be probed.
valProbe	The values of the moderator that will be used to probe the effect of the other independent factor.

Details

Before using this function, researchers need to make the products of the indicators between the first-order factors using mean centering (Marsh, Wen, & Hau, 2004). Note that the double-mean centering may not be appropriate for probing interaction if researchers are interested in simple intercepts. The mean or double-mean centering can be done by the indProd function. The indicator products can be made for all possible combination or matched-pair approach (Marsh et al., 2004). Next, the hypothesized model with the regression with latent interaction will be used to fit all original indicators and the product terms. See the example for how to fit the product term below. Once the lavaan result is obtained, this function will be used to probe the interaction.

Let that the latent interaction model regressing the dependent variable (Y) on the independent variable (X) and the moderator (Z) be

$$Y = b_0 + b_1 X + b_2 Z + b_3 X Z + r,$$

probe2WayMC 39

where b_0 is the estimated intercept or the expected value of Y when both X and Z are 0, b_1 is the effect of X when Z is 0, b_2 is the effect of Z when X is 0, b_3 is the interaction effect between X and Z, and T is the residual term.

For probing two-way interaction, the simple intercept of the independent variable at each value of the moderator (Aiken & West, 1991; Cohen, Cohen, West, & Aiken, 2003; Preacher, Curran, & Bauer, 2006) can be obtained by

$$b_{0|X=0,Z} = b_0 + b_2 Z.$$

The simple slope of the independent variable at each value of the moderator can be obtained by

$$b_{X|Z} = b_1 + b_3 Z.$$

The variance of the simple intercept formula is

$$Var(b_{0|X=0,Z}) = Var(b_0) + 2ZCov(b_0, b_2) + Z^2Var(b_2)$$

where Var denotes the variance of a parameter estimate and Cov denotes the covariance of two parameter estimates.

The variance of the simple slope formula is

$$Var(b_{X|Z}) = Var(b_1) + 2ZCov(b_1, b_3) + Z^2Var(b_3)$$

Wald statistic is used for test statistic.

Value

A list with two elements:

- 1. SimpleIntercept The intercepts given each value of the moderator. This element will be shown only if the factor intercept is estimated (e.g., not fixed as 0).
- 2. SimpleSlope The slopes given each value of the moderator.

In each element, the first column represents the values of the moderators specified in the valProbe argument. The second column is the simple intercept or simple slope. The third column is the standard error of the simple intercept or simple slope. The fourth column is the Wald (z) statistic. The fifth column is the p-value testing whether the simple intercepts or slopes are different from 0.

probe2WayRC

Probing two-way interaction on the residual-centered latent interaction

Description

Probing interaction for simple intercept and simple slope for the residual-centered latent two-way interaction (Pornprasertmanit, Schoemann, Geldhof, & Little, submitted)

Usage

```
probe2WayRC(fit, nameX, nameY, modVar, valProbe)
```

probe2WayRC 41

Arguments

fit The lavaan model object used to evaluate model fit

nameX The vector of the factor names used as the predictors. The first-order factor will

be listed first. The last name must be the name representing the interaction term.

nameY The name of factor that is used as the dependent variable.

modVar The name of factor that is used as a moderator. The effect of the other indepen-

dent factor on each moderator variable value will be probed.

valProbe The values of the moderator that will be used to probe the effect of the other

independent factor.

Details

Before using this function, researchers need to make the products of the indicators between the first-order factors and residualize the products by the original indicators (Lance, 1988; Little, Bovaird, & Widaman, 2006). The process can be automated by the indProd function. Note that the indicator products can be made for all possible combination or matched-pair approach (Marsh et al., 2004). Next, the hypothesized model with the regression with latent interaction will be used to fit all original indicators and the product terms. See the example for how to fit the product term below. Once the lavaan result is obtained, this function will be used to probe the interaction.

The probing process on residual-centered latent interaction is based on transforming the residual-centered result into the no-centered result. See Pornprasertmanit, Schoemann, Geldhof, and Little (submitted) for further details. Note that this approach based on a strong assumption that the first-order latent variables are normally distributed. The probing process is applied after the no-centered result (parameter estimates and their covariance matrix among parameter estimates) has been computed. See the probe2WayMC for further details.

Value

A list with two elements:

- 1. SimpleIntercept The intercepts given each value of the moderator. This element will be shown only if the factor intercept is estimated (e.g., not fixed as 0).
- 2. SimpleSlope The slopes given each value of the moderator.

In each element, the first column represents the values of the moderators specified in the valProbe argument. The second column is the simple intercept or simple slope. The third column is the standard error of the simple intercept or simple slope. The fourth column is the Wald (z) statistic. The fifth column is the p-value testing whether the simple intercepts or slopes are different from 0.

probe3WayMC 43

probe3WayMC Probing two-way interaction on the residual-centered latent tion	nterac-
--	---------

Description

Probing interaction for simple intercept and simple slope for the no-centered or mean-centered latent two-way interaction

Usage

```
probe3WayMC(fit, nameX, nameY, modVar, valProbe1, valProbe2)
```

Arguments

fit	The lavaan model object used to evaluate model fit
nameX	The vector of the factor names used as the predictors. The three first-order factors will be listed first. Then the second-order factors will be listeed. The last element of the name will represent the three-way interaction. Note that the fourth element must be the interaction between the first and the second variables. The fifth element must be the interaction between the first and the third variables. The sixth element must be the interaction between the second and the third variables.
nameY	The name of factor that is used as the dependent variable.
modVar	The name of two factors that are used as the moderators. The effect of the independent factor on each combination of the moderator variable values will be probed.
valProbe1	The values of the first moderator that will be used to probe the effect of the independent factor.
valProbe2	The values of the second moderator that will be used to probe the effect of the independent factor.

Details

Before using this function, researchers need to make the products of the indicators between the first-order factors using mean centering (Marsh, Wen, & Hau, 2004). Note that the double-mean centering may not be appropriate for probing interaction if researchers are interested in simple intercepts. The mean or double-mean centering can be done by the indProd function. The indicator products can be made for all possible combination or matched-pair approach (Marsh et al., 2004). Next, the hypothesized model with the regression with latent interaction will be used to fit all original indicators and the product terms. See the example for how to fit the product term below. Once the lavaan result is obtained, this function will be used to probe the interaction.

Let that the latent interaction model regressing the dependent variable (Y) on the independent variable (X) and two moderators (Z and W) be

$$Y = b_0 + b_1 X + b_2 Z + b_3 W + b_4 X Z + b_5 X W + b_6 Z W + b_7 X Z W + r,$$

where b_0 is the estimated intercept or the expected value of Y when X, Z, and W are 0, b_1 is the effect of X when Z and W are 0, b_2 is the effect of Z when X and W is 0, b_3 is the effect of W when X and Z are 0, b_4 is the interaction effect between X and Z when W is 0, b_5 is the interaction

44 probe3WayMC

effect between X and W when Z is 0, b_6 is the interaction effect between Z and W when X is 0, b_7 is the three-way interaction effect between X, Z, and W, and r is the residual term.

For probing three-way interaction, the simple intercept of the independent variable at the specific values of the moderators (Aiken & West, 1991) can be obtained by

$$b_{0|X=0,Z,W} = b_0 + b_2 Z + b_3 W + b_6 Z W.$$

The simple slope of the independent variable at the specific values of the moderators can be obtained by

$$b_{X|Z,W} = b_1 + b_3 Z + b_4 W + b_7 Z W.$$

The variance of the simple intercept formula is

$$Var\left(b_{0|X=0,Z,W}\right) = Var\left(b_{0}\right) + Z^{2}Var\left(b_{2}\right) + W^{2}Var\left(b_{3}\right) + Z^{2}W^{2}Var\left(b_{6}\right) + 2ZCov\left(b_{0},b_{2}\right) + 2WCov\left(b_{0},b_{3}\right) + 2ZVar\left(b_{1},b_{2}\right) + 2ZVar\left(b_{2}\right) + 2ZVar\left(b_{3}\right) + 2Z$$

where Var denotes the variance of a parameter estimate and Cov denotes the covariance of two parameter estimates.

The variance of the simple slope formula is

$$Var\left(b_{X|Z,W}\right) = Var\left(b_{1}\right) + Z^{2}Var\left(b_{4}\right) + W^{2}Var\left(b_{5}\right) + Z^{2}W^{2}Var\left(b_{7}\right) + 2ZCov\left(b_{1},b_{4}\right) + 2WCov\left(b_{1},b_{5}\right) + 2ZWCov\left(b_{1},b_{2}\right) + 2ZW$$

Wald statistic is used for test statistic.

Value

A list with two elements:

- 1. SimpleIntercept The intercepts given each value of the moderator. This element will be shown only if the factor intercept is estimated (e.g., not fixed as 0).
- 2. SimpleSlope The slopes given each value of the moderator.

In each element, the first column represents the values of the first moderator specified in the valProbe1 argument. The second column represents the values of the second moderator specified in the valProbe2 argument. The third column is the simple intercept or simple slope. The fourth column is the standard error of the simple intercept or simple slope. The fifth column is the Wald (z) statistic. The sixth column is the p-value testing whether the simple intercepts or slopes are different from 0.

Probing three-way interaction on the residual-centered latent interac-
```

Description

Probing interaction for simple intercept and simple slope for the residual-centered latent three-way interaction (Pornprasertmanit, Schoemann, Geldhof, & Little, submitted)

Usage

```
probe3WayRC(fit, nameX, nameY, modVar, valProbe1, valProbe2)
```

Arguments

fit	The lavaan model object used to evaluate model fit
nameX	The vector of the factor names used as the predictors. The three first-order factors will be listed first. Then the second-order factors will be listeed. The last element of the name will represent the three-way interaction. Note that the fourth element must be the interaction between the first and the second variables. The fifth element must be the interaction between the first and the third variables. The sixth element must be the interaction between the second and the third variables.
nameY	The name of factor that is used as the dependent variable.
modVar	The name of two factors that are used as the moderators. The effect of the independent factor on each combination of the moderator variable values will be probed.
valProbe1	The values of the first moderator that will be used to probe the effect of the independent factor.
valProbe2	The values of the second moderator that will be used to probe the effect of the independent factor.

Details

Before using this function, researchers need to make the products of the indicators between the first-order factors and residualize the products by the original indicators (Lance, 1988; Little, Bovaird, & Widaman, 2006). The process can be automated by the indProd function. Note that the indicator products can be made for all possible combination or matched-pair approach (Marsh et al., 2004). Next, the hypothesized model with the regression with latent interaction will be used to fit all original indicators and the product terms (Geldhof, Pornprasertmanit, Schoemann, & Little, in press). See the example for how to fit the product term below. Once the lavaan result is obtained, this function will be used to probe the interaction.

probe3WayRC 47

The probing process on residual-centered latent interaction is based on transforming the residual-centered result into the no-centered result. See Pornprasertmanit, Schoemann, Geldhof, and Little (submitted) for further details. Note that this approach based on a strong assumption that the first-order latent variables are normally distributed. The probing process is applied after the no-centered result (parameter estimates and their covariance matrix among parameter estimates) has been computed See the probe3WayMC for further details.

Value

A list with two elements:

- 1. SimpleIntercept The intercepts given each value of the moderator. This element will be shown only if the factor intercept is estimated (e.g., not fixed as 0).
- 2. SimpleSlope The slopes given each value of the moderator.

In each element, the first column represents the values of the first moderator specified in the valProbe1 argument. The second column represents the values of the second moderator specified in the valProbe2 argument. The third column is the simple intercept or simple slope. The fourth column is the standard error of the simple intercept or simple slope. The fifth column is the Wald (z) statistic. The sixth column is the p-value testing whether the simple intercepts or slopes are different from 0.

reliability 49

reliability

Calculate reliability values of factors

Description

Calculate reliability values of factors by coefficient omega

Usage

reliability(object)

Arguments

object

The lavaan model object provided after running the cfa, sem, growth, or lavaan functions.

Details

The coefficient alpha (Cronbach, 1951) can be calculated by

$$\alpha = \frac{k}{k-1} \left[1 - \frac{\sum_{i=1}^{k} \sigma_{ii}}{\sum_{i=1}^{k} \sigma_{ii} + 2\sum_{i < j} \sigma_{ij}} \right],$$

where k is the number of items in a factor, σ_{ii} is the item i observed variances, σ_{ij} is the observed covariance of items i and j.

The coefficient omega (Raykov, 2001) can be calculated by

$$\omega = \frac{\left(\sum_{i=1}^{k} \lambda_{i}\right)^{2} Var\left(\psi\right)}{\left(\sum_{i=1}^{k} \lambda_{i}\right)^{2} Var\left(\psi\right) + \sum_{i=1}^{k} \theta_{ii} + 2\sum_{i < j} \theta_{ij}},$$

where λ_i is the factor loading of item i, ψ is the factor variance, θ_{ii} is the variance of measurement errors of item i, and θ_{ij} is the covariance of measurement errors from item i and j.

The second coefficient omega (Bentler, 1972, 2009) can be calculated by

$$\omega_2 = 1 - \frac{\mathbf{1}'\Theta\mathbf{1}}{\mathbf{1}'\hat{\Sigma}\mathbf{1}},$$

where Θ is the measurement error covariance matrix, $\hat{\Sigma}$ is the model-implied covariance matrix, and 1 is the k-dimensional vector of 1. The first and the second coefficients omega will have different values if there are dual loadings (or the existence of method factors). The first coefficient omega can be viewed as the reliability controlling for the other factors. The second coefficient omega can be viewed as the unconditional reliability.

The third coefficient omega (McDonald, 1999) can be calculated by

$$\omega_3 = 1 - \frac{\mathbf{1}'\Theta\mathbf{1}}{\mathbf{1}'\Sigma\mathbf{1}},$$

50 reliability

where Σ is the observed covariance matrix. If the model fits the data well, the third coefficient omega will be similar to the other two. Note that if there is a directional effect in the model, all coefficients omega will use the total factor variances, which is calculated by the <code>impliedFactorCov</code> function.

If measurement errors are not correlated, the last term in the denominator of the middle expression is dropped. For the categorical items, the reliability indices are calculated from the latent variable underlying the categorical items (i.e., using polychoric/polyserial correlations). Therefore, the coefficient alpha from this function may be not the same as the standard alpha calculation for categorical items. Researchers may check the alpha function in the psych package for the standard coefficient alpha calculation.

Value

Reliability values (coefficient alpha, coefficients omega) of each factor in each group

reliabilityL2 for reliability value of a desired second-order factor

reliabilityL2 51

reliabilityL2

Calculate the reliability values of a second-order factor

Description

Calculate the reliability values (coefficient omega) of a second-order factor

Usage

reliabilityL2(object, secondFactor)

Arguments

object The lavaan model object provided after running the cfa, sem, growth, or lavaan

functions that has a second-order factor

secondFactor The name of the second-order factor

Details

The first formula of the coefficient omega (in the reliability) will be mainly used in the calculation. The model-implied covariance matrix of a second-order factor model can be separated into three sources: the second-order factor, the uniqueness of the first-order factor, and the measurement error of indicators:

$$\hat{\Sigma} = \Lambda \boldsymbol{B} \Phi_2 \boldsymbol{B}' \Lambda' + \Lambda \Psi_u \Lambda' + \Theta,$$

where Σ is the model-implied covariance matrix, Λ is the first-order factor loading, \boldsymbol{B} is the second-order factor loading, Φ_2 is the covariance matrix of the second-order factors, Ψ_u is the covariance matrix of the unique scores from first-order factors, and Θ is the covariance matrix of the measurement errors from indicators. Thus, the proportion of the second-order factor explaining the total score, or the coefficient omega at Level 1, can be calculated:

$$\omega_{L1} = \frac{\mathbf{1}' \Lambda \boldsymbol{B} \boldsymbol{\Phi}_2 \boldsymbol{B}' \Lambda' \mathbf{1}}{\mathbf{1}' \Lambda \boldsymbol{B} \boldsymbol{\Phi}_2 \boldsymbol{B}' \Lambda' \mathbf{1} + \mathbf{1}' \Lambda \boldsymbol{\Psi}_u \Lambda' \mathbf{1} + \mathbf{1}' \boldsymbol{\Theta} \mathbf{1}},$$

where 1 is the k-dimensional vector of 1 and k is the number of observed variables. When model-implied covariance matrix among first-order factors (Φ_1) can be calculated:

$$\Phi_1 = \mathbf{B}\Phi_2\mathbf{B}' + \Psi_u,$$

Thus, the proportion of the second-order factor explaining the varaince at first-order factor level, or the coefficient omega at Level 2, can be calculated:

$$\omega_{L2} = \frac{\mathbf{1}_F' B \Phi_2 B' \mathbf{1}_F}{\mathbf{1}_F' B \Phi_2 B' \mathbf{1}_F + \mathbf{1}_F' \Psi_u \mathbf{1}_F},$$

where $\mathbf{1}_F$ is the F-dimensional vector of 1 and F is the number of first-order factors.

The partial coefficient omega at Level 1, or the proportion of observed variance explained by the second-order factor after partialling the uniqueness from the first-order factor, can be calculated:

$$\omega_{L1} = \frac{\mathbf{1}' \Lambda \boldsymbol{B} \boldsymbol{\Phi}_2 \boldsymbol{B}' \Lambda' \mathbf{1}}{\mathbf{1}' \Lambda \boldsymbol{B} \boldsymbol{\Phi}_2 \boldsymbol{B}' \Lambda' \mathbf{1} + \mathbf{1}' \boldsymbol{\Theta} \mathbf{1}},$$

Note that if the second-order factor has a direct factor loading on some observed variables, the observed variables will be counted as first-order factors.

52 residualCovariate

Value

Reliability values at Levels 1 and 2 of the second-order factor, as well as the partial reliability value at Level 1

Author(s)

Sunthud Pornprasertmanit (University of Kansas; <psunthud@ku.edu>)

See Also

reliability for the reliability of the first-order factors.

Examples

residualCovariate

Residual centered all target indicators by covariates

Description

This function will regress target variables on the covariate and replace the target variables by the residual of the regression analysis. This procedure is useful to control the covariate from the analysis model (Geldhof, Pornprasertmanit, Schoemann, & Little, in press).

Usage

```
residualCovariate(data, targetVar, covVar)
```

Arguments

data The desired data to be transformed.

targetVar Varible names or the position of indicators that users wish to be residual centered

(as dependent variables)

covVar Covariate names or the position of the covariates using for residual centering (as

independent variables) onto target variables

Value

The data that the target variables replaced by the residuals

Author(s)

Sunthud Pornprasertmanit (University of Kansas; <psunthud@ku.edu>)

runMI 53

References

Geldhof, G. J., Pornprasertmanit, S., Schoemann, A. M., & Little, T. D. (in press). Orthogonalizing through residual centering: Applications and caveats. *Educational and Psychological Measurement*.

See Also

indProd For creating the indicator products with no centering, mean centering, double-mean centering, or residual centering.

Examples

```
dat <- residualCovariate(attitude, 2:7, 1)</pre>
```

runMI

Multiply impute and analyze data using lavaan

Description

This function takes data with missing observations, multiple imputes the data, runs a SEM using lavaan and combines the results using Rubin's rules. Note that parmeter estimates and standard errors are pooled by the Rubin's (1987) rule. The chi-square statistics and the related fit indices are pooled by the method described in "chi" argument. SRMR is calculated based on the average model-implied means and covariance matrices across imputations.

Usage

```
runMI(model, data, m, miArgs=list(), chi="all", miPackage="Amelia",
seed=12345, fun, ...)
cfa.mi(model, data, m, miArgs=list(), miPackage="Amelia", chi="all",
seed=12345, ...)
sem.mi(model, data, m, miArgs=list(), miPackage="Amelia", chi="all",
seed=12345, ...)
growth.mi(model, data, m, miArgs=list(), miPackage="Amelia", chi="all",
seed=12345, ...)
lavaan.mi(model, data, m, miArgs=list(), miPackage="Amelia", chi="all",
seed=12345, ...)
```

Arguments

model	lavaan syntax for the the model to be analyzed.	
data	Data frame with missing observations or a list of data frames where each data frame is one imputed data set (for imputed data generated outside of the function). If a list of data frames is supplied, then other options can be left at the default.	
m	Number of imputations wanted.	
miArgs	Addition arguments for the multiple-imputation function. The arguments should be put in a list (see example below).	
miPackage	Package to be used for imputation. Currently these functions only support "Amelia" or "mice" for imputation.	

54 runMI

chi	The method to combine the chi-square. Can be one of the following: "MR" for the method proposed for Meng & Rubin (1992), "Mplus" for the method used in Mplus (Asparouhov & Muthen, 2010), "LMRR" for the method proposed by Li, Meng, Raghunathan, & Rubin (1991), and "all" to show the three methods in the output. The default is "all".
seed	Random number seed to be used in imputations.
fun	The character of the function name used in running lavaan model ("cfa", "sem", "growth", "lavaan").
• • •	Other arguments to be passed to the specified lavaan function ("cfa", "sem", "growth", "lavaan").

Value

The lavaanStar object which contains the original lavaan object (where the appropriate parameter estimates, appropriate standard errors, and chi-squares are filled), the additional fit-index values of the null model, which need to be adjusted to multiple datasets, and the information from pooling multiple results.

skew

Finding skewness

Description

Finding skewness (g1) of an object

Usage

```
skew(object, population=FALSE)
```

Arguments

object A vector used to find a skewness

population TRUE to compute the parameter formula. FALSE to compute the sample statistic

formula.

skew 57

Details

The skewness computed is g1. The parameter skewness γ_2 formula is

$$\gamma_2 = \frac{\mu_3}{\mu_2^{3/2}},$$

where μ_i denotes the *i* order central moment.

The excessive kurtosis formula for sample statistic g_2 is

$$g_2 = \frac{k_3}{k_2^2},$$

where k_i are the i order k-statistic.

The standard error of the skewness is

$$Var(\hat{g}_2) = \frac{6}{N}$$

where N is the sample size.

Value

A value of a skewness with a test statistic if the population is specified as FALSE

58 splitSample

splitSample Randomly Split a Data Set into Halves

Description

This function randomly splits a data set into two halves, and saves the resulting data sets to the same folder as the original.

Usage

```
splitSample(dataset,path="default", div=2, type="default", name="splitSample")
```

Arguments

dataset	The original data set to be divided. Can be a file path to a .csv or .dat file (headers will automatically be detected) or an R object (matrix or dataframe). (Windows users: file path must be specified using FORWARD SLASHES ONLY.)
path	File path to folder for output data sets. NOT REQUIRED if dataset is a filename. Specify ONLY if dataset is an R object, or desired output folder is not that of original data set. If path is specified as "object", output data sets will be returned as a list, and not saved to hard drive.
div	Number of output data sets. NOT REQUIRED if default, 2 halves.
type	Output file format ("dat" or "csv"). NOT REQUIRED unless desired output formatting differs from that of input, or dataset is an R object and csv formatting is desired.
name	Output file name. NOT REQUIRED unless desired output name differs from that of input, or input dataset is an R object. (If input is an R object and name is not specified, name will be "splitSample".)

Details

This function randomly orders the rows of a data set, divides the data set into two halves, and saves the halves to the same folder as the original data set, preserving the original formatting. Data set type (.csv or .dat) and formatting (headers) are automatically detected, and output data sets will preserve input type and formatting unless specified otherwise. Input can be in the form of a file path (.dat or .csv), or an R object (matrix or dataframe). If input is an R object and path is default, output data sets will be returned as a list object.

Value

dataL List of output data sets. ONLY IF dataset is an R object and path is default. Otherwise, output will saved to hard drive with the same formatting as input.

Author(s)

Corbin Quick (University of Kansas; <corbinq@ku.edu>)

splitSample 59

```
#### Input is .dat file
#splitSample("C:/Users/Default/Desktop/MYDATA.dat")
#### Output saved to "C:/Users/Default/Desktop/" in .dat format
#### Names are "MYDATA_s1.dat" and "MYDATA_s2.dat"
#### Input is R object
##Split CO2 dataset from the datasets package
library(datasets)
splitMyData <- splitSample(CO2, path="object")</pre>
summary(splitMyData[[1]])
summary(splitMyData[[2]])
#### Output object splitMyData becomes list of output data sets
#### Input is .dat file in "C:/" folder
#splitSample("C:/testdata.dat", path = "C:/Users/Default/Desktop/", type = "csv")
#### Output saved to "C:/Users/Default/Desktop/" in .csv format
#### Names are "testdata_s1.csv" and "testdata_s2.csv"
#### Input is R object
#splitSample(myData, path = "C:/Users/Default/Desktop/", name = "splitdata")
#### Output saved to "C:/Users/Default/Desktop/" in .dat format
#### Names are "splitdata_s1.dat" and "splitdata_s2.dat"
